Revision table

Revision	Date	Reason and description
A	January 2, 2011	Original document
B	January 13, 2011	New section – General construction details
		Modification to the booster section
		Add information to the recovery section
		Add information to the Performance / motor section
C	January 14, 2011	Modification to the fin dimensions
		Add flutter analysis
D	January 27, 2011	Correction to Fins construction details
E	January 29, 2011	Motor retention, shear pins and drag separation calculation
F	February 4, 2011	Drag separation of the upper section and rocket weight correction (motor performance)
G	March 5, 2011	New fin flutter calculation, add 2 layers of CF
H	April 17, 2011	Construction corrections
I	June 15, 2011	Change electric diagram, and use switch to shunt the e-matches
J	June 26, 2011	Add a missing 5cm tube on the ebay !

Documentation Package

General Construction details

Booster section

- 2 layers of 6oz fiberglass with West Epoxy will be applied on the tube to make it stronger. Even if for the first flight the maximum speed will be 282 m/s (0.85 Mach) and by PML specification their tubes can withstand speed up to 0.85 Mach without fiberglass. Having the rocket fibre glassed, we can assume a strength improvement of 50% so the tube will be able to withstand a speed of 1,2 Mach.
- All centering and bulkhead are linked together with 3 threaded rods
- 5 centering are epoxied on the motor tube and fillets are done on both sides to increase the strength. Those 5 rings will transfer the engine force to the rocket.
- The motor retainer chosen is the Aeropack 98mm. The motor retainer is attached to the lower centering with 12 8-32 Stainless Cap screws and threaded inserts.

Fins

- The fins are epoxied on the motor tube with Aeropoxy PR2032 and the join is reinforced with carbon fibre. The outside of the motor casing cannot be hotter than 200°C (as per Tripoli certification). The phenolic tube is providing isolation, the motor is burning for less than 5 seconds, not enough time to transmit a lot of heat to the epoxy, than the rocket is decelerating to reach apogee, in this phase the motor is already cooling and less stress is apply on the fins. Aeropoxy and carbon fibre were choose because they can support over 200°F.
- Extra strong material, G10 1/8", with 2 layers of carbon fibre plus a tip to tip carbon fibre will be used to increase the resistance to fin fluttering. See Fin Section for analysis.
- Epoxy fillets are applied on the outside tubes and the fins to reinforce the bound with the rocket.

Coupler

- The coupler is reinforce with 1 layer of 6oz fiberglass plus a layer of carbon fibre inside the coupler, to help the epoxy bind the fiberglass and the coupler, a balloon is inflated inside the coupler, putting pressure on the assembly.
- The bulkhead that will host the U-bolt is doubled with a G-10 bulkhead and a layer of epoxy on the outside.

Drogue tube

- 2 layers of 6oz fiberglass are applied to reinforce the tube to make it stronger.

Main parachute section

- 2 layers of 6oz fiberglass are applied to reinforce the tube to make it stronger.

Electronic bay

- The electronic bay is reinforced with 2 layers of 6oz carbon fibre inside the coupler
- The bulkheads that will host the U-bolt are reinforced with a layer of epoxy to make it stronger and make it easier to clean.

Epoxy

- The epoxy use for temperature sensitive location will be Aeropoxy PR2032 and hardener PH3630.
- The epoxy use in this project will be the West Epoxy (105) and hardener (205).
- JB Weld will be used for high temperature section, like on motor tube.

Design limitation

Under the stress of the lift off the main parachute section and drogue section (airframe) are the weakest point of this design. The choice of using fiberglass instead of carbon fibre will limit the use of the rocket under Mach 1,2.

In the recovery system, the weakest link is the U-bolt, this why all bulkheads on which U-bolts are attached are doubled on the inside with a G10 bulkhead to increase the strength of the plywood and washers are present on both side to distribute the charges.

Materials lists

Motor section

- 1X 63,5cm PML fiberglass wrapped 15,316cm phenolic tube
- 3X custom fins of 0,125" G10
- 4X centering rings 0.5" - Plywood 14,859cm to 10,211cm
- 1X Motor mount Tube PML 4" phenolic tube 70,5cm
- 1X Motor retainer 98mm, Aero-pack
- 1X PML coupler 98mm, 27cm – Reinforce inside with 2 layers (1 fiberglass (6oz) and 1 Carbon fibre (6oz))
- 4X Hexa bolt 1/4" x 20 lock knot
- 1X bulkhead 0,5" – Plywood 14,401cm – Reinforce on the outside with a layer of epoxy
- 1X bulkhead 1/8" – G10 14,895cm
- 1X centering 1/8" – G10 14,895cm to 10,211cm
- 1X 5/16" U-bolt
- 4X 5/16" Hexa-bolt lock for the U-Bolt
- 2X 5/16" washer
- 1X plat for the U-Bolt
- 3X threaded rods 1/4"-20 x 77cm
- 6X Hexa-bolt 1/4" - 20
- 2X Launch button large (1515)
- 12X 8-32 Stainless Cap Screws

Drogue section

- 1X 5 cm PML fiberglass wrapped 15,316cm phenolic tube
- 1X 58,5cm PML fiberglass wrapped 15,316cm phenolic tube
- 1X Cert 3 – Drogue parachute by SkyAngle
- 1X Nomex blanket
- 1X Kevlar sleeve 2" x 30"
- 3X Quick link stainless steel 1400lbs
- 1X Tubular nylon strap 3/4" x 35', 15Kn

Main chute section

- 1X 107 cm PML fiberglass wrapped 15,316cm phenolic tube
- 1X Cert 3 – Xlarge parachute by SkyAngle
- 1X Nomex blanket
- 1X Kevlar sleeve 2" x 30"
- 3X Quick link stainless steel 1400lbs
- 1X Tubular nylon strap 3/4" x 40', 15Kn

Electronic bay

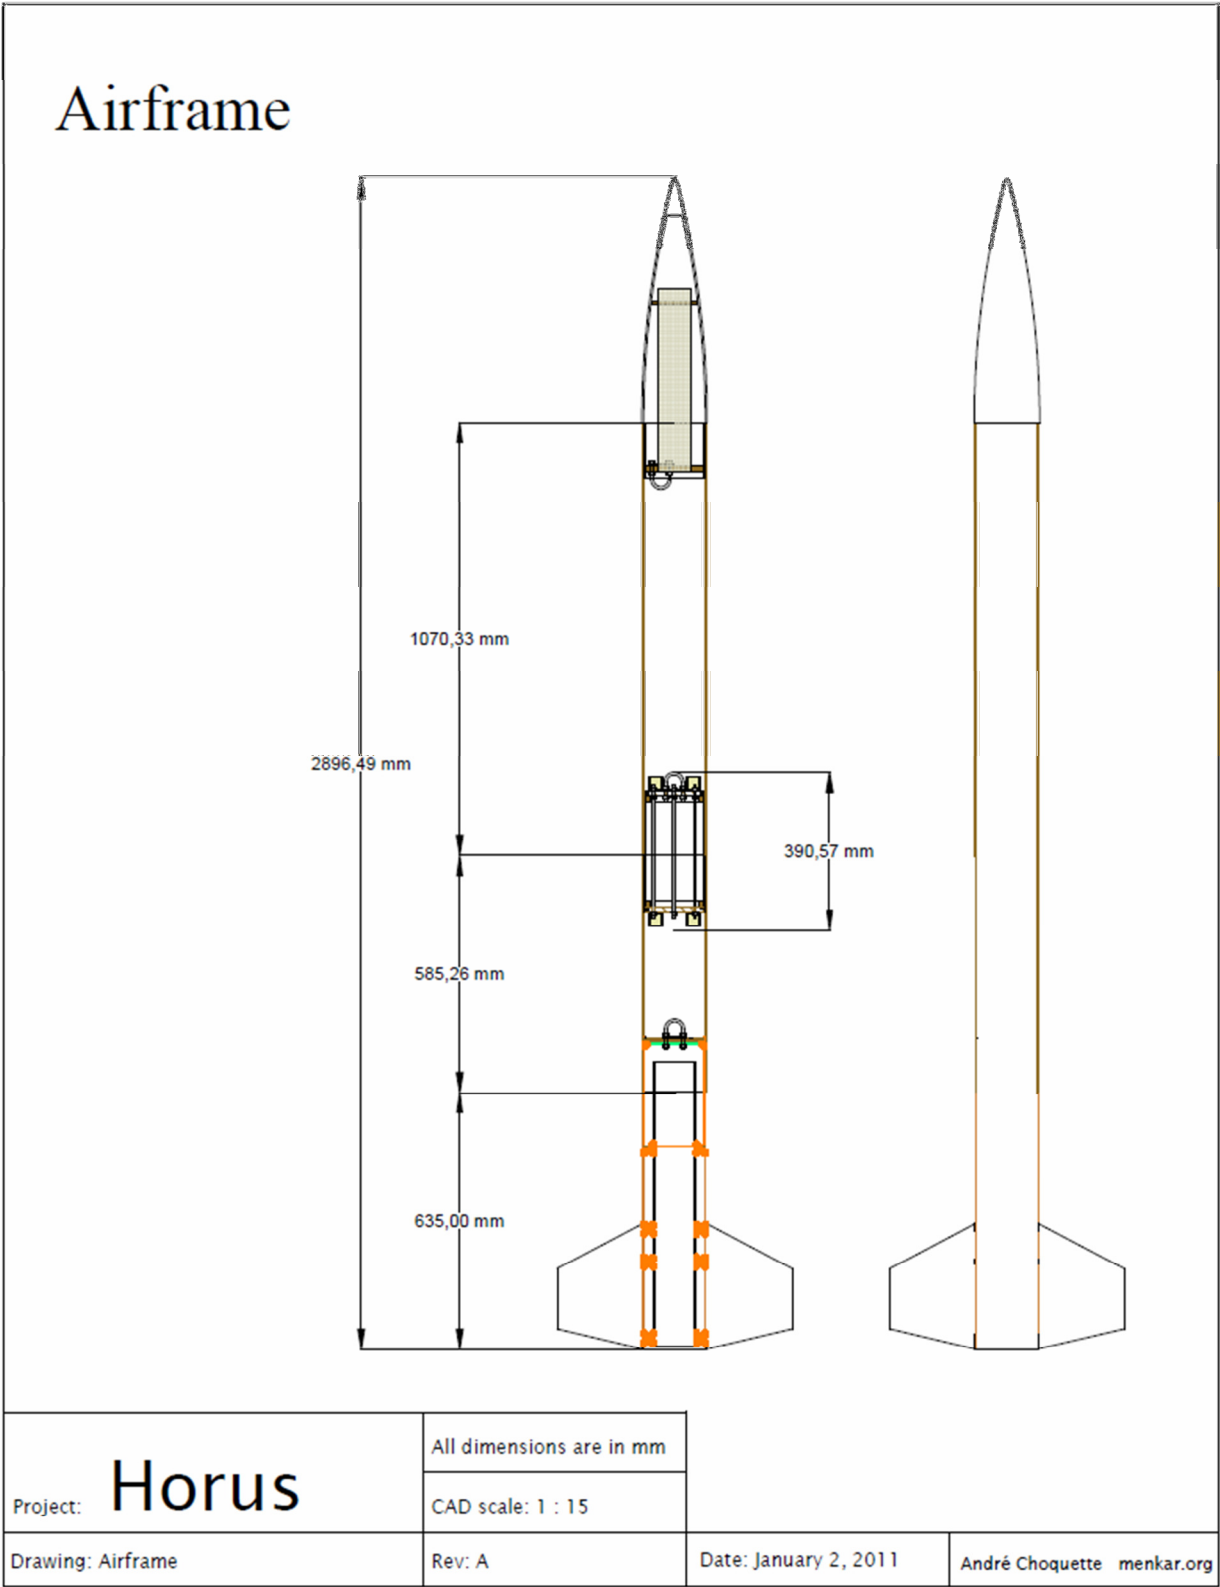

- 1X 30 cm PML phenolic coupler 148mm – Reinforce inside with 2 layer of fiberglass (6oz)
- 2X bulkhead 0,5" – Plywood 14,401cm – Reinforce on the outside with a layer of Epoxy (West)
- 2X U-bolt 5/16"
- 8X Hexa-bolt lock for the U-bolt
- 4X washer
- 2X plat for the U-Bolt
- 3X 1/4" x 20 rod , 32,6cm
- 4X PVC end cap 3/4"
- 2X Seal rings 0,5" – Plywood 14,401cm
- 8X #6-32 screws to secure Main and Drogue section to the electronic bay

Nose cone

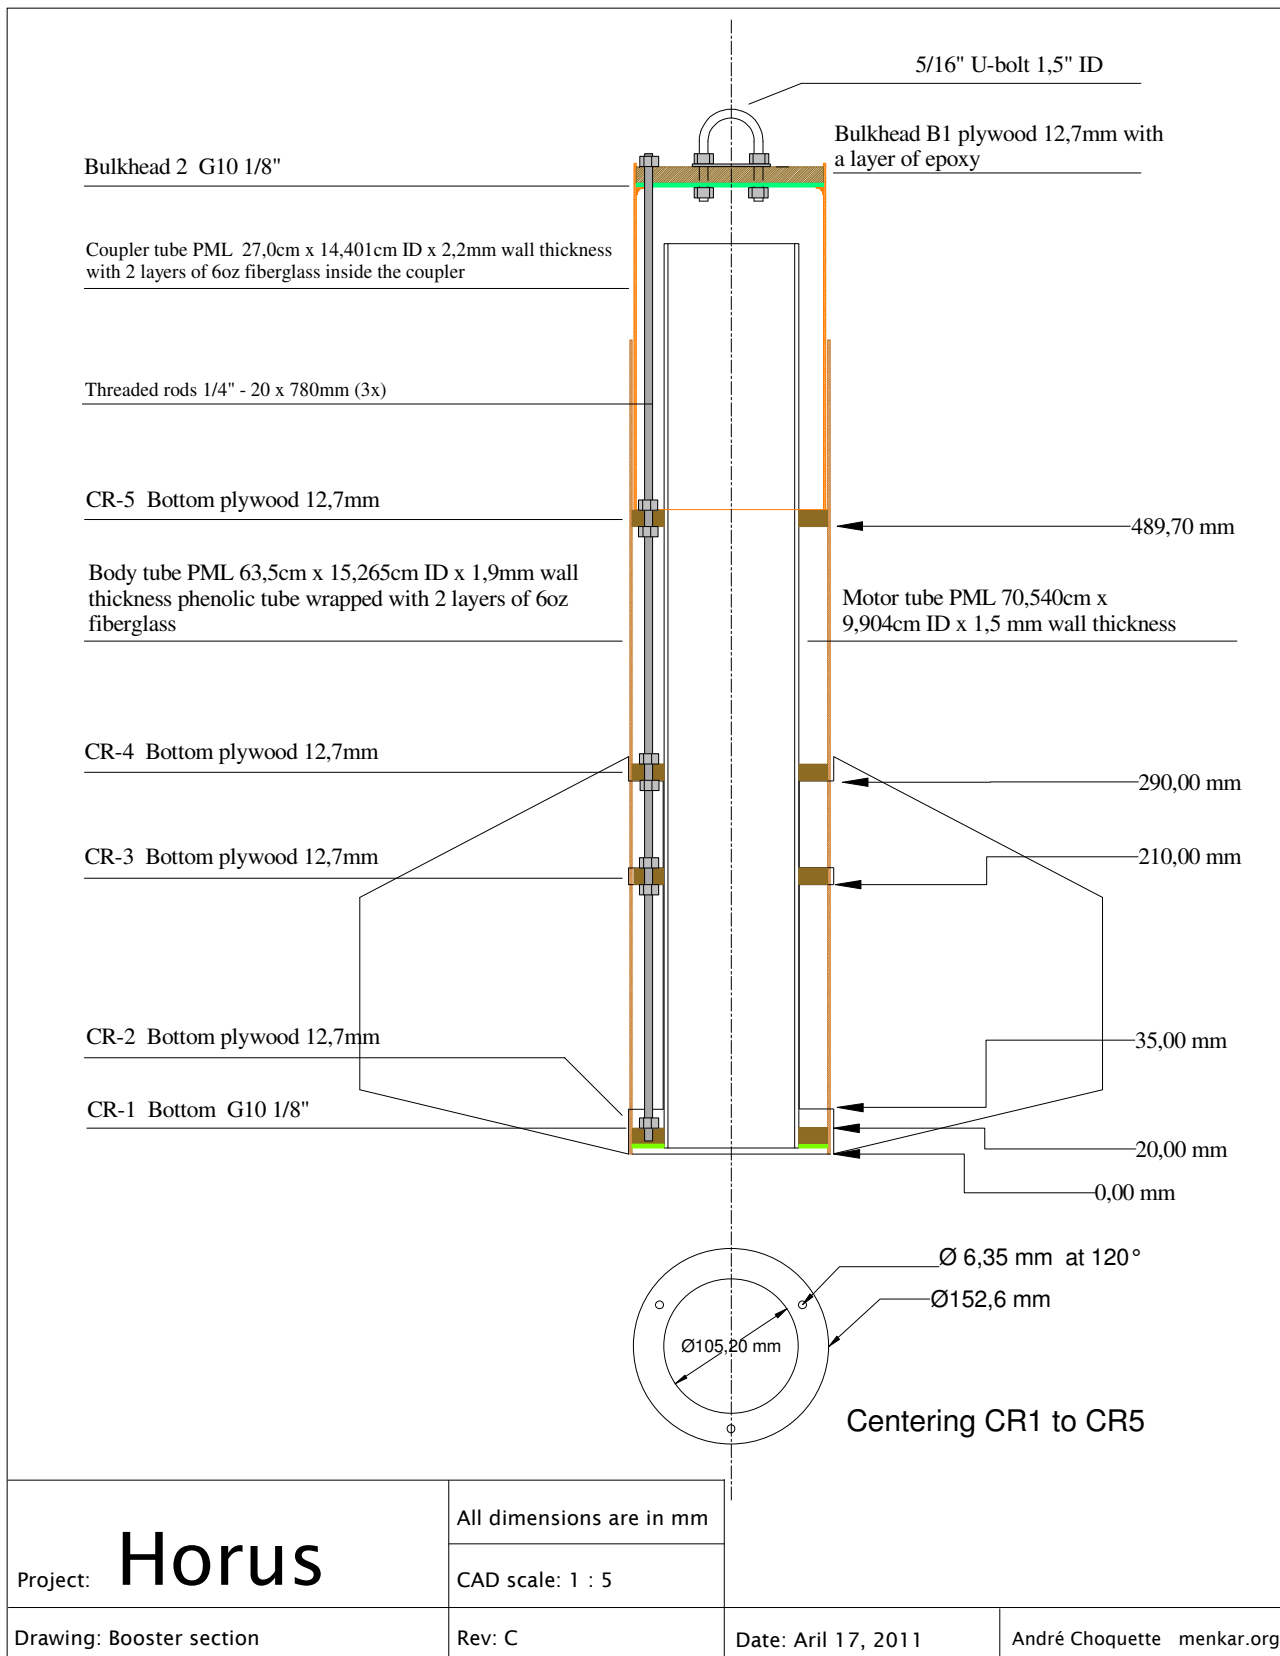

- PML Fiberglass nose cone FNC-6.0 length 60,960 cm, diameter 15.494 cm
- 1X centering 1/4" – Plywood 11,47cm to 7,95cm
- 1X centering 1/2" – Plywood 14,16cm to 7,95cm
- 1X bulkhead 1/8" – G10 9,66cm
- 1X 45,0cm PML phenolic tube for the GPS transmitter
- 1X 5/16" U-bolt
- 4X 5/16" Hexa-bolt lock for the U-Bolt
- 2X 5/16" washer
- 1X plat for the U-Bolt

Fin dimensions

Project: Horus	All dimensions are in mm		
	CAD scale: 1: 2		
Drawing:	Rev: B	Date: January 15, 2011	André Choquette menkar.org

Fins

Fin flutter analysis

Fin flutter analysis is based on Trapezoidal fin shape:

Root chord: 31cm (12,2")
Span: 17cm (6,69")
Tip chord: 15cm (5,91")
Sweep length: 13cm (5,11")

I don't have specialized software to calculate fin flutter. I used a special spreadsheet to evaluate the flutter velocity. The spreadsheet is based on NACA Technical Note 4197 which presents a simplified method for calculating fin flutter velocity based on the method of Theoderson. NACA TN-4197 has confirming data up to "at least Mach 1.3", so this analysis may not hold up for higher Mach numbers. NACA TN-4197 covers three different types of flutter: pitch-bending flutter, stall flutter, and torsion-bending flutter. The flutter that we experience in amateur rocketry is torsion-bending flutter, that is, flutter due to the fins twisting and bending because they are not stiff enough.

$$V_f = \frac{(V_a)(G_E)}{\left(\frac{p}{p_0}\right)\left(\frac{\lambda+1}{2}\right)\left[\frac{39.3(A^3)}{\left(\frac{t}{c}\right)^3(A+2)}\right]}$$

	Description	Value
Va	Speed of sound	766,22 mph
Ge	Shear modulus	7,69Gpa (G10) - 53,85Gpa (CF) – 30,00Gpa (FG)
A	Aspect ratio	0,92 computed with the spreadsheet
P / P0	Air pressure / Air pressure at sea level	Estimated at 1 (launch site are closed to sea level in Quebec)
T	Fin thickness	0,125" (G10) and 0,150" (G10 + 2 layers of CF)
C	Root chord	12,2"
λ	Tapper ratio (tip chord / root chord)	5,91" / 12,2" = 0.4844

For 0,125" plain G10 the Shred velocity (2.2x flutter velocity) will be $2.2 \times 304 = \mathbf{668,8 \text{ mph}}$. Considering that the fins will be covered tip to tip with carbon fibre giving a new thickness of 0,150" and an adjusted Shear modulus of $(6,152 + 10,77) = 16,922$.

For 0.150" G10 and 2 layers of CF the Shred velocity will be $2.2 \times 594 = \mathbf{1306 \text{ mph or } 583 \text{ m/s}}$. This value is well over the speed of any "M" impulse motor. For my L4 certification, the motor I choose will bring the rocket to a maximum speed of 282m/s. This is giving me a margin of more than 100%.

Now, for 6 layers of CF, 3 on each side, the thickness reach 0.166". The combined G10 and CF have a Shear Modulus of $(.75 * 7.69 + .25 * 53.58)$ 19.09 this is giving the fin a Shred velocity of $2.2 \times 734 = 1468$ **mph or 656 m/s**. Even if this value is a bit optimistic, it is way over the 282m/s estimated for the certification flight. The biggest motor that can be used in Horus is the CTI 3400WT 4 grains and the maximum velocity is 420 m/s (Mach 1.26), well under the calculated shred velocity.

Recovery System

Electronics

In the main electronic bay two altimeters:

- 1- Missile Works RRC2 mini, drogue at the apogee and main at 1000'
- 2- Featherweight Altimeters Raven, drogue at apogee +1 sec and main at 900'

Each altimeter has its own apogee and main black powder canister, for a total of 4 canisters and e-matches.

The RRC2 is used in the 2X 9V battery configuration, one for the altimeter itself and the second one for the charges.

The Raven is used with 1X 9V battery, the Raven do include an aerogel ultra-capacitor to keep the altimeter alive in case of temporary disconnection (10 to 20 sec.).

A Beeline GPS is located in the nose cone (70cm band).
Frequency: 429,750 MHz

Parachute

- Drogue, Cert 3 – Drogue by SkyAngle
- Main, Cert 3 – Xlarge parachute by SkyAngle

Descent rate under the Drogue: 14,3 m/s (51 km/h) - 46,9 ft./s (31.9 mi/h) (Rocksim)

Descent rate under the Main parachute: 4,3 m/s (15,4 km/h) - 14 ft./s (9,6 mi/h) (Rocksim)

Shock cords are protected with Kevlar sleeves on the first 30", the parachute and the other 35' of shock cords are protected by Nomex blankets.

Given the size of the main parachute, predicted deceleration forces are predicted to be significant. Thus techniques such as configuring the cord to dissipate energy and the utilization of stretch cords will be utilized to minimize the deployment forces for the main parachute.

Ejection charge calculation

The ejection charge for the project will be FFFG black powder (the only available and work like the 4F). The pressure I want to reach is about 15 psi. For 15 Psi, we can use the formula:

$$F = PA, F=\text{Force}, P=\text{Pressure}, A=\text{Area} \rightarrow P = 15 * \pi * (D/2)^2 \rightarrow P = 424$$

$$N = 0.00052 * FL \quad F=424, L = \text{length of tube to pressurize}$$

$$\text{Drogue:} \quad N = 0.00052 * 424 * 11.77'' = 2,5g$$

$$\text{Main:} \quad N = 0.00052 * 424 * 30.9'' = 6.8g \text{ rounded to } 7,0g$$

Those numbers have to be confirmed with ground static tests. Those tests will be used to check that the ejection charge can separate and eject the parachute with the 3x #4-40 nylon shear pins.

Drag separation

Nose code

Drag separation can occur immediately after main motor burn out due to the differential acceleration between the different components of the airframe. Let's assume there is no friction between the nose cone and the airframe. The maximum force applied on the nose cone will be:

Nose cone weight: 1,1kg (including bulkheads, U-bolt and electronic tube)

Harness and parachute: 2kg

Total: 3,1kg

Maximum deceleration (Calculated with Rocksim) at 4,9 sec. : $-2,294 = 2,294 * 9,81\text{m/s}^2 = 22,5\text{m/s}^2$

$F = M * A = 3,1 * 22,5 = 69,8 \text{ N} \rightarrow 15,69 \text{ lbf}$

Upper section

Nose cone weight: 1,1kg (including bulkheads, U-bolt and electronic tube)

Harness and parachute: 2kg

Electronic bay:

Drogue section (including harness and drogue):

Total: 13,3kg

Maximum deceleration (Calculated with Rocksim) at 4,9 sec. : $-2,294 = 2,294 * 9,81\text{m/s}^2 = 22,5\text{m/s}^2$

$F = M * A = 13,3 * 22,5 = 299,3 \text{ N} \rightarrow 67,3 \text{ lbf}$

Shear pins sizing

#4-40 Nylon 6/6 screws have a shear Strength of 9600 to 10500 psi.

With a diameter (smaller) of 0,08130" or a section area of 0,0051912 sq. inch, a nylon screw has at minimum a shear strength of $0,0051912 * 9600 = 49,8 \text{ lbf}$.

Three of them will have 149,4 lbf of strength, 10 times more than the maximum deceleration produced by at the burnout of the main motor for the nose cone and main section and more than 2 times for the upper rocket sections (drogue, electronic bay, main and nose cone).

#2-56 Nylon 6/6 screws have a shear Strength of 9600 to 10500 psi.

With a diameter (smaller) of 0,06410" or a section area of 0,0032271 sq. inch, a nylon screw has at minimum a shear strength of $0,0032271 * 9600 = 30,9 \text{ lbf}$.

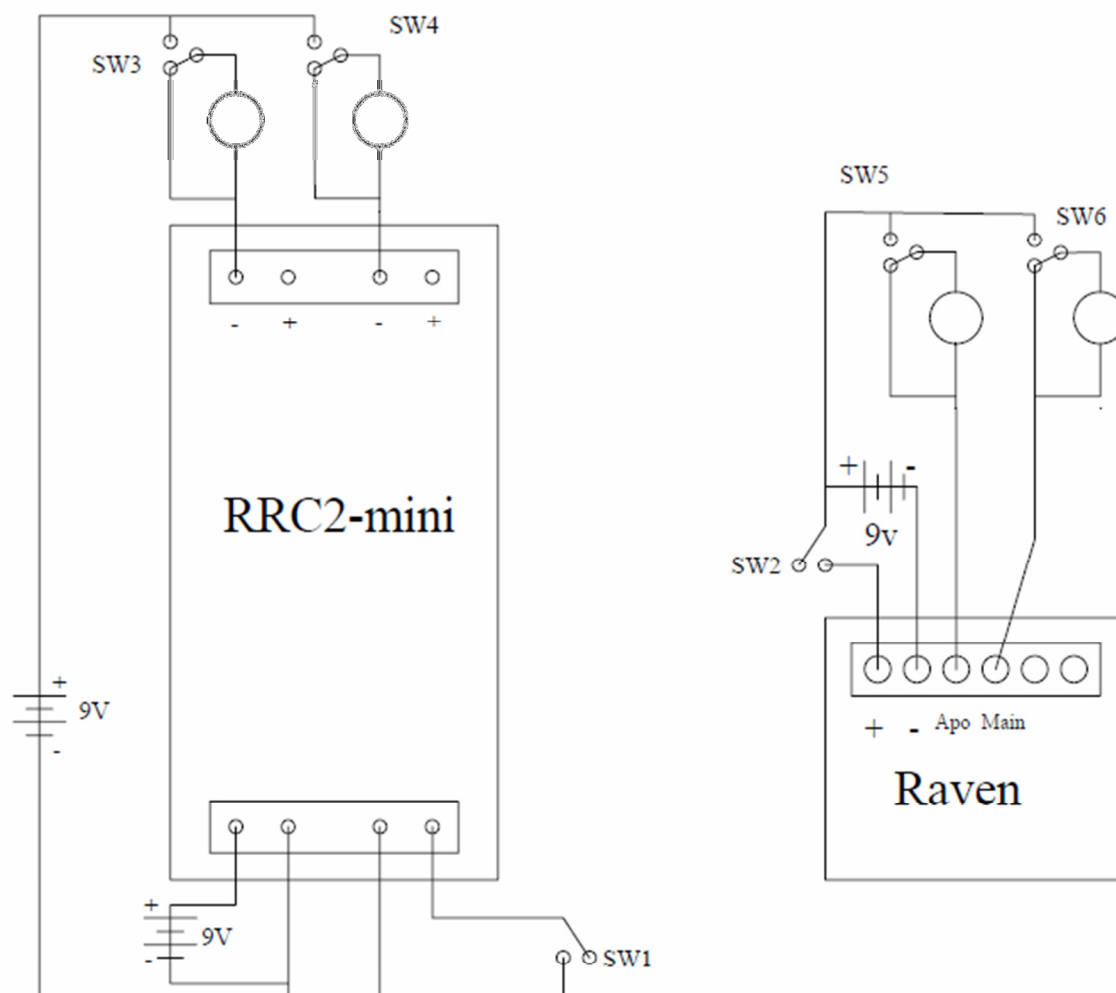

Three of them will have 92,9 lbf of strength, almost 7 times more than the maximum deceleration produced by at the burnout of the main motor and more than 1,5 times for the upper rocket sections (drogue, electronic bay, main and nose cone).

Using 3x #4-40 Nylon 6/6 screws will give a better margin of safety against premature ejection of the main parachute. The ejection charges will produce more than 400lbf more than enough to shear the 3 #4-40 screws.

Ground tests will be run to confirm those numbers.

Wiring diagram

Wiring diagram

Sw1 and Sw2 are key switches,
Sw3 to Sw6 are 110v-220v rotary switches

Project: Horus	All dimensions are in mm		
	CAD scale:		
Drawing: Wiring	Rev: B	Date: June 15, 2011	André Choquette menkar.org

Performance

Weight empty: 16,6 Kg - 36,6 lbs.

Weight loaded: 23,3 Kg - 51,4 lbs.

Motor: CTI 7579 M1520 BS

Burn time: 4,9 sec.

Thrust to weight ratio: 6,65

Maximum altitude: 3450m - 11300 ft.

Maximum Gees: 9,55

Maximum speed: 282 m/s (1015 km/h) - 925 ft./s (630 mi/h)

Time to apogee: 26,5s

Speed at launch guide departure (3m) : 19,1 m/s (69 km/h) - 63 ft./s (43 mi/h)

CG from the nose cone: 203,1cm

CP from the nose cone: 227,9cm

Static margin: 1,60

Flight simulation by: Rocksim 9.0

L4_4me
Length: 294.880 cm , Diameter: 15.646 cm , Span diameter: 49.646 cm
Mass 22750.757 g , Selected stage mass 22750.757 g
CG: 203.180 cm, CP: 227.931 cm, Margin: 1.60
Engines: [M1520-BS-None,]

Pre-launch Checklist

Assembly checklist

Ejection system

- | | | |
|--------------------------|-----|---|
| <input type="checkbox"/> | 1- | Verify if the Raven is correctly program |
| <input type="checkbox"/> | | a. Drogue - Apogee + 1 second |
| <input type="checkbox"/> | | b. Main – 900' |
| <input type="checkbox"/> | 2- | Verify if the RRC2-mini is correctly program |
| <input type="checkbox"/> | | a. Drogue - Apogee |
| <input type="checkbox"/> | | b. Main – 1000' |
| <input type="checkbox"/> | 3- | Put all master arming switches OFF (1x main and 1x drogue charges) |
| <input type="checkbox"/> | 4- | Make sure both power switches are OFF |
| <input type="checkbox"/> | 5- | Install fresh batteries in all electronics, total 3 (2x RRC2 and 1x Raven), should read > 9,5v |
| <input type="checkbox"/> | 6- | Verify all wires to the altimeters |
| <input type="checkbox"/> | 7- | Install the electronic sled in the bay |
| <input type="checkbox"/> | 8- | Seal the altimeter bay |
| <input type="checkbox"/> | 9- | Install an electronic match in each Drogue canister, secure with tape |
| <input type="checkbox"/> | 10- | Install an electronic match in each Main canister, secure with tape |
| <input type="checkbox"/> | 11- | Turn ON all switches |
| <input type="checkbox"/> | 12- | Confirm the continuity, RRC2 should emit 3 short beeps and the Raven should emit 2 beeps (one per charge) |
| <input type="checkbox"/> | 13- | Turn OFF all switches |
| <input type="checkbox"/> | 14- | Main chute Canister - Place 7g of black powder per canister, secure with wadding and tape |
| <input type="checkbox"/> | 15- | Drogue chute Canister - Place 2,5g of black powder per canister, secure with wadding and tape |

Recovery system

- | | | |
|--------------------------|----|---|
| <input type="checkbox"/> | 1- | Connect the Drogue shock cord with Nomex to the electronic bay |
| <input type="checkbox"/> | 2- | Install Drogue section tube to the electronic bay and tighten the 4 screws |
| <input type="checkbox"/> | 3- | Connect the Drogue shock cord to the booster section |
| <input type="checkbox"/> | 4- | Pack shock cord and drogue chute in the lower body section with Nomex blanket |
| <input type="checkbox"/> | 5- | Install the 2 shear pin |
| <input type="checkbox"/> | 6- | Connect the Main shock cord with Nomex to the electronic bay |
| <input type="checkbox"/> | 7- | Install Main section tube to the electronic bay and tighten the 4 screws |
| <input type="checkbox"/> | 8- | Connect the Main shock cord to the nose cone |
| <input type="checkbox"/> | 9- | Pack shock cord and the main chute in the upper body section with Nomex blanket |

GPS recovery system

- | | | |
|--------------------------|----|--|
| <input type="checkbox"/> | 1- | Turn ON the Beeline GPS |
| <input type="checkbox"/> | 2- | Turn ON the receiver on 429,750 MHz on the second VFO |
| <input type="checkbox"/> | 3- | Verify the reception of the APRS packet |
| <input type="checkbox"/> | 4- | Install the sled in the nose cone |
| <input type="checkbox"/> | 5- | Secure with 3x #6-32 screws |
| <input type="checkbox"/> | 6- | Install the nose cone and secure it with the 3 shear pin |

Motor assembly

- | | | |
|--------------------------|----|--|
| <input type="checkbox"/> | 1- | Assemble Motor hardware and re-load per CTI instructions |
| <input type="checkbox"/> | 2- | Slip motor assembly into the motor tube |
| <input type="checkbox"/> | 3- | Screw the Aero-pack retainer tightly over aft end motor |
| <input type="checkbox"/> | 4- | Confirm the center of gravity |
| <input type="checkbox"/> | 5- | Tape the igniter and screw driver to the motor tube |

Final assembly check

- | | | |
|--------------------------|----|--|
| <input type="checkbox"/> | 1- | All #6-32 screws holding airframes to electronic bay are tight |
| <input type="checkbox"/> | 2- | All #4-40 shear pins are in place |
| <input type="checkbox"/> | 3- | Motor retainer is tight |
| <input type="checkbox"/> | 4- | All static port and vent hole are clear of debris |
| <input type="checkbox"/> | 5- | Fill out launch card at RCO table |

Pre-flight checklist

Launch check

- ☐ 1- Turn the power switch ON for the RRC2, it should emit a single long beep (no charge detected)
- ☐ 2- Turn the power switch ON for the Raven, it should emit a single low beep (no charge detected)
- ☐ 3- Turn ON the charges switch for the RRC2
- ☐ 4- RRC2 - Confirm the continuity, should have 3 short beeps
 - a. **If readings are not ok: turn OFF all electronics and shunt all the charges**
- ☐ 5- Turn ON the charge switch for the Raven
- ☐ 6- Raven - Confirm the continuity, should have 2 high pitch beep (one per charge)
 - a. **If readings are not ok: turn OFF all electronics and shunt all the charges**
- ☐ 7- Install the igniter in the motor
- ☐ 8- Connect the launch system leads to the motor igniter
- ☐ 9- Check for continuity at launch battery supply

Pad failure

- ☐ 1- Wait for the authorization of the LCO or RSO before going to the launch pad
- ☐ 2- Disconnect the igniter
- ☐ 3- Remove the igniter
- ☐ 4- **Turn OFF all the electronics and shunt the charges**

Post-flight checklist

- ☐ 1- Bring help to carry the rocket back
- ☐ 2- Bring radios, APRS receiver
- ☐ 3- Secure landing site
- ☐ 4- **Turn OFF all the electronics and shunt the charges**
- ☐ 5- Bring back the sections
- ☐ 6- Bring the rocket to the L4CC for inspection
